Register Allocation

Part of the compiler's back end

Critical properties

- Produce correct code that uses no more than k registers
- Minimize added work from loads and stores that spill values
- Minimize space used to hold spilled values
- Operate efficiently

$O(n)$, $O(n \log_2 n)$, maybe $O(n^2)$, but not $O(2^n)$

Notation: The literature on register allocation consistently uses k as the number of registers available on the target system.

r0 holds base address for local variables

@x is constant offset of x from r0

Register Allocation

Consider a fragment of assembly code (or ILOC)

```
loadI  2      => r1    // r1 <- 2
loadAI r0, @b  => r2    // r2 <- b
mult    r1, r2  => r3    // r3 <- 2 · b
loadAI r0, @a  => r4    // r4 <- a
sub     r4, r3  => r5    // r5 <- a - (2 · b)
```

From the allocation perspective, these registers are virtual or pseudo-registers

The Problem

- At each instruction, decide which values to keep in registers
 - Note: each pseudo-register in the example is a value
- Simple if $|values| \leq |registers|$
- Harder if $|values| > |registers|$
- The compiler must automate this process

Register Allocation

The Task

- At each point in the code, pick the values to keep in registers
- Insert code to move values between registers & memory
 - No transformations (leave that to optimization & scheduling)
- Minimize inserted code — both dynamic & static measures
- Make good use of any extra registers

Allocation versus assignment

- Allocation is deciding which values to keep in registers
- Assignment is choosing specific registers for values
- This distinction is often lost in the literature

The compiler must perform both allocation & assignment

Background issues

- The register allocator takes as input a code that is almost completely compiled
- It has been scanned, parsed, checked, analysed, optimised, rewritten as target machine code, and, perhaps, scheduled
- Many previously made decisions influence the task of the allocator:
 - Memory-to-memory versus register-to- register memory model
 - Allocation versus Assignment
 - Register Classes

Register-to -register vs. memory-to-memory

- With a register-to -register earlier phases in the compiler directly encode the knowledge about ambiguous memory references: with this model unambiguous values are kept into virtual registers
- In a register-to -register the code produced by the previous step is not legal
- In a memory-to-memory model, the code is legal before allocation; allocation improve performance
- In a memory-to-memory model the allocator does not have any knowledge and this can limit its ability

Allocation

Allocation is an hard problem that in its general formulation is NP-complete.

The allocation of a single basic block with **one size data** value can be done in **polynomial time under strong hypothesis**:

- each value have to be stored to memory at the end of its lifetime
- the spilling of value has **uniform cost**

almost any additional complexity makes the problem NP-complete

Allocation vs. Assignment

- Once we have reduced the demand for registers, the assignment can be done in polynomial time for a machine with one kind of registers

Register Classes

- General purpose registers
 - Integer values and memory addresses
 - Floating-point registers
-
- If the compiler uses different kind of registers for different kinds of data, it can allocate each class independently: the problem can be simplified
 - If the different kinds of data overlap, the compiler must allocate them together: the allocation can become more complex

Basic Blocks in Assembly Code (or ILOC)

Definition

- A **basic block** is a maximal length segment of straight-line (i.e., branch free) code

Importance

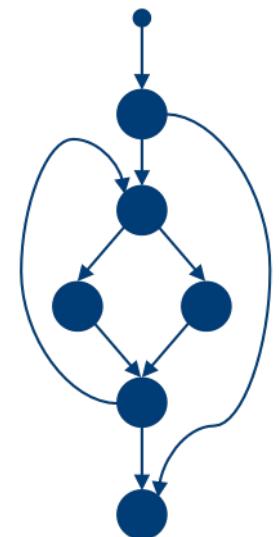

- Strongest facts are provable for branch-free code
 - If any statement executes, they all execute
 - Execution is totally ordered
- Ignore, for the moment, exceptions

Role of Basic Blocks in Optimization

- Many techniques for improving basic blocks
- Simplest problems
- Strongest methods

Local Register Allocation

- What is “local” ? (different from “regional” or “global”)
 - A local transformation operates on basic blocks
 - Many optimizations are done on a local scale or scope
- Does local allocation solve the problem?
 - It produces good register use inside a block
 - Inefficiencies can arise at boundaries between blocks
- How many passes can the allocator make?
 - This is an off-line problem
 - As many passes as it takes, within reason
 - You can do a fine job in a couple of passes

Blocks in a Control-flow Graph (CFG)

Register Allocation

Optimal register allocation is hard

Local Allocation

- Simplified cases $\Rightarrow O(n)$
- Real cases \Rightarrow NP-Complete

Local Assignment

- Single size, no spilling $\Rightarrow O(n)$
- Two sizes \Rightarrow NP-Complete

Global Allocation

- NP-Complete for 1 register
- NP-Complete for k registers
(most sub-problems are NPC, too)

Global Assignment

- NP-Complete

Real compilers face real problems

ILOC

- Pseudo-code for a simple, abstracted RISC machine
 - generated by the instruction selection process
- Simple, compact data structures

a - 2 × b	loadI	2	$\Rightarrow r_1$
	loadAI	$r_0, @b$	$\Rightarrow r_2$
	mult	r_1, r_2	$\Rightarrow r_3$
	loadAI	$r_0, @a$	$\Rightarrow r_4$
	sub	r_4, r_3	$\Rightarrow r_5$

Nearly assembly code

- simple three-address code
- RISC-like addressing modes
 - I, AI, AO
- unlimited virtual registers
 - (register-to-register vs memory-to-memory)

ILOC

- Pseudo-code for a simple, abstracted RISC machine
 - generated by the instruction selection process
- Simple, compact data structures

$a - 2 \times b$

loadI	2		r ₁
loadAI	r ₀	@b	r ₂
add	r ₁	r ₂	r ₃
loadAI	r ₀	@a	r ₄
sub	r ₄	r ₃	r ₅

Quadruples:

- table of k × 4 small integers
- simple record structure
- easy to reorder
- all names are explicit

Observations

The Register Allocator does not need to "understand" the code

- It needs to distinguish definitions from uses
 - Definitions might need to store a spilled value
 - Uses might need to load a spilled value
- ILOC makes definitions and uses pretty clear
 - The assignment arrow, \Rightarrow , separates uses from definitions
 - Except on the store operation, which uses all its register operands
 - That is the point of the arrow!
- Your allocator needs to know, by opcode, how many definitions and how many uses it should see
 - Beyond that, the meaning of the ILOC is somewhat irrelevant to the allocator

Observations

A value is **live** between its **definition** and its **uses**

- Find definitions ($x \leftarrow \dots$) and uses ($y \leftarrow \dots x \dots$)
- From definition to last use is its **live range**
 - How does a **second definition** affect this?
- Can represent live range as an interval $[i,j]$ (in block)

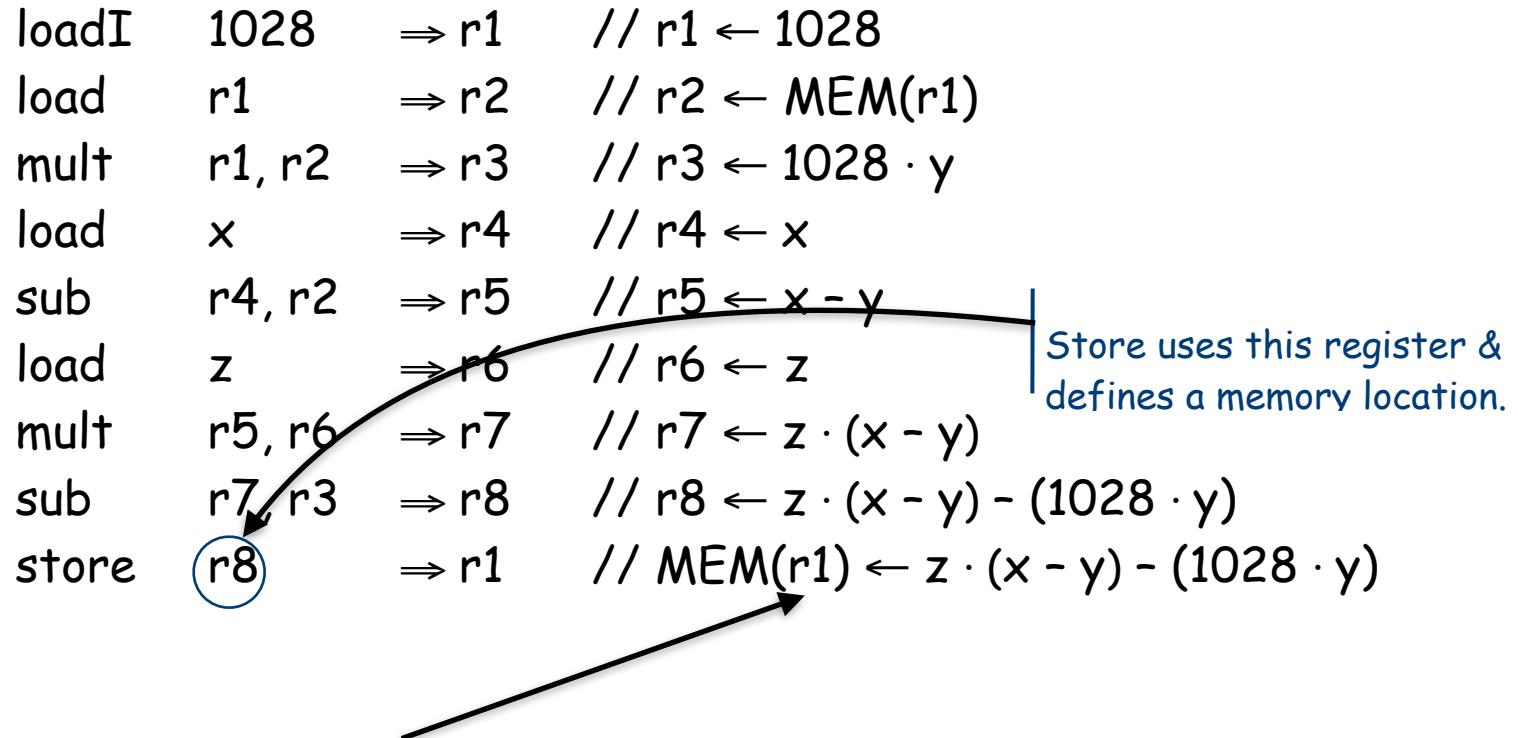

Let MAXLIVE be the maximum, over each instruction i in the block, of the number of values (pseudo-registers) live at i .

- If $\text{MAXLIVE} \leq k$, allocation should be easy:
no need to reserve F registers for spilling
- If $\text{MAXLIVE} > k$, some values must be spilled to memory:
need to reserve F registers for spilling

Finding live ranges is harder in the global case

Concrete Example of MAXLIVE

Sample code sequence

The code uses 1028 as both an address and as a constant in the computation.

The intent is to create a long live range for pedagogical purposes. Remember, the allocator does not need to understand the computation. It just needs to preserve the computation.

Concrete Example of MAXLIVE

Live ranges in the example

loadI	1028	$\Rightarrow r1$	// r1
load	r1	$\Rightarrow r2$	// r1 r2
mult	r1, r2	$\Rightarrow r3$	// r1 r2 r3
load	x	$\Rightarrow r4$	// r1 r2 r3 r4
sub	r4, r2	$\Rightarrow r5$	// r1 r3 r5
load	z	$\Rightarrow r6$	// r1 r3 r5 r6
mult	r5, r6	$\Rightarrow r7$	// r1 r3 r7
sub	r7, r3	$\Rightarrow r8$	// r1 r8
store	r8	$\Rightarrow r1$	//

A pseudo-register is live after an operation if it has been defined & has a use in the future

Concrete Example of MAXLIVE

Live ranges in the example

loadI	1028	$\Rightarrow r1$	// r1	
load	r1	$\Rightarrow r2$	// r1 r2	
mult	r1, r2	$\Rightarrow r3$	// r1 r2 r3	
load	x	$\Rightarrow r4$	// r1 r2 r3 r4	
sub	r4, r2	$\Rightarrow r5$	// r1 r3 r5	
load	z	$\Rightarrow r6$	// r1 r3 r5 r6	
mult	r5, r6	$\Rightarrow r7$	// r1 r3	r7
sub	r7, r3	$\Rightarrow r8$	// r1	r8
store	r8	$\Rightarrow r1$	//	

Remember, r1 is a use,
not a definition

MAXLIVE is 4

Compute these "live" sets in a backward pass over the code.
Start with live as the empty set.
At each op, remove target & add operands

Local Allocation: Top-down Versus Bottom-up

Top-down allocator

- Work from external notion of what is important
- Assign registers in priority order
- Save some registers for the values relegated to memory

Bottom-up allocator

- Work from detailed knowledge about problem instance
- Incorporate knowledge of partial solution at each step
- Handle all values uniformly

Top-down Allocator

The idea

- The most heavily used values should reside in a register
- Reserve registers for use in spills, say r registers

Algorithm

- Count the number of occurrences of each virtual register in the block (from 2 to $\text{maxLength}(\text{block})$)
 - Sort the registers according to the previous info
 - Allocate first $k - r$ values to registers
 - Rewrite code to reflect these choices
- { Move values with no register into memory
(add LOADs & STOREs)

Programmers applied this idea by hand in the 70's & early 80's

Top-down Allocator

How many registers must the allocator reserve?

- Need registers to compute spill addresses & load values
- Number depends on target architecture
 - Typically, must be able to load 2 values
- Reserve these registers for spilling

What if $k - r < |\text{values}| < k$?

- Remember that the underlying problem is NP-Complete
- The allocator can either
 - Check for this situation
 - Adopt a more complex strategy
 - Accept the fact that the technique is an approximation

Back to the Example

Top down (3 registers)

loadI	1028	$\Rightarrow r1$	// r1	r1 is used more often than r3
load	r1	$\Rightarrow r2$	// r1 r2	
mult	r1, r2	$\Rightarrow r3$	// r1 r2 r3	
load	x	$\Rightarrow r4$	// r1 r2 r3 r4	
sub	r4, r2	$\Rightarrow r5$	// r1 r3 r5	
load	z	$\Rightarrow r6$	// r1 r3 r5 r6	
mult	r5, r6	$\Rightarrow r7$	// r1 r3	r7
sub	r7, r3	$\Rightarrow r8$	// r1	r8
store	r8	$\Rightarrow r1$	//	

Note that this assumes that no extra register is needed for spilling

Back to the Example

Top down (3 registers, need 2 for operands)

loadI 1028 ⇒ r1 // r1

r1 is used more often than r3

load r1 ⇒ r2 // r1 r2

mult r1, r2 ⇒ r3 // r1 r2 r3

load x ⇒ r4 // r1 r2 r3 r4

spill r3

sub r4, r2 ⇒ r5 // r1 r3 r5

load z ⇒ r6 // r1 r3 r5 r6

mult r5, r6 ⇒ r7 // r1 r3

r7

sub r7, r3 ⇒ r8 // r1

r8 restore r3

store r8 ⇒ r1 //

Note that this assumes that no extra register is needed for spilling

An Example

Top down (3 registers, need 2 for operands)

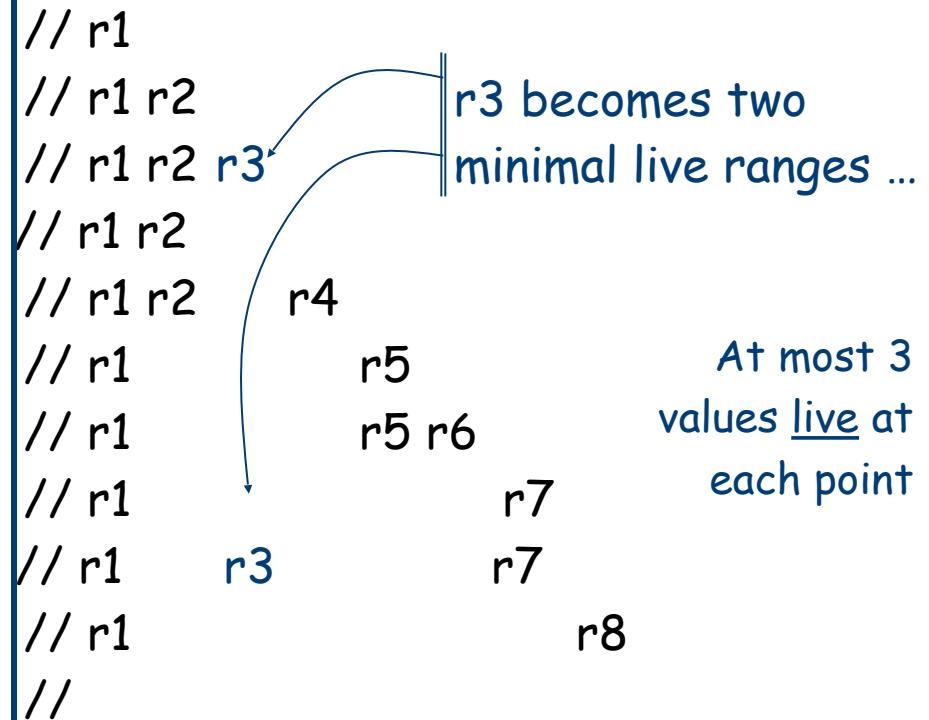

loadI	1028	$\Rightarrow r1$	// r1		
load	r1	$\Rightarrow r2$	// r1 r2		
mult	r1, r2	$\Rightarrow r3$	// r1 r2 r3		
store	r3		$\Rightarrow 16$	// r1 r2	r3 becomes two minimal live ranges ...
load	x	$\Rightarrow r4$	// r1 r2	r4	
sub	r4, r2	$\Rightarrow r5$	// r1	r5	
load	z	$\Rightarrow r6$	// r1	r5 r6	
mult	r5, r6	$\Rightarrow r7$	// r1	r7	
load	16	$\Rightarrow r3$	// r1	r3	r7
sub	r7, r3	$\Rightarrow r8$	// r1		r8
store	r8	$\Rightarrow r1$	//		

"spill" and "restore" become stores and loads

An Example

Top down (3 registers)

loadI	1028	$\Rightarrow r1$
load	r1	$\Rightarrow r2$
mult	r1, r2	$\Rightarrow r3$
store	r3	$\Rightarrow 16$
load	x	$\Rightarrow r4$
sub	r4, r2	$\Rightarrow r5$
load	z	$\Rightarrow r6$
mult	r5, r6	$\Rightarrow r7$
load	16	$\Rightarrow r3$
sub	r7, r3	$\Rightarrow r8$
store	r8	$\Rightarrow r1$

The two short versions of r3 each overlap with fewer values, which simplifies the allocation problem. Such “spilling” will (eventually) create a code where the allocator can succeed.

An Example

Top down (3 registers)

loadI	1028	$\Rightarrow r1$	// r1			
load	r1	$\Rightarrow r2$	// r1 r2			
mult	r1, r2	$\Rightarrow r3$	// r1 r2 r3			
store	r3	$\Rightarrow 16$	// r1 r2			
loadI	x	$\Rightarrow r4$	// r1 r2	r4		
sub	r4, r2	$\Rightarrow r5$	// r1		r5	
loadI	z	$\Rightarrow r6$	// r1		r5 r6	
mult	r5, r6	$\Rightarrow r7$	// r1			r7
load	16 $\Rightarrow r3$	// r1	r3	r7		possible delay
sub	r7, r3	$\Rightarrow r8$	// r1			r8
store	r8	$\Rightarrow r1$	//			

This code is slower than the original, but it works correctly on a target machine with only three (available) registers.
Correctness is a virtue.

Weakness of the top down approach to allocation

- A physical register is dedicated to a virtual register for an entire block

Bottom-up Allocator

The idea:

- Focus on replacement rather than allocation
- Keep values used “soon” in registers

Algorithm (not optimal!):

- Start with empty register set
- Load on demand
- When no register is available, free one

Replacement:

- Spill the value whose next use is farthest in the future
- Prefer clean values (not to be stored, constant or values already in memory) to dirty (to be stored).

An Example

Bottom up (3 registers)

loadI	1028	$\Rightarrow r1$	// r1	
load	r1	$\Rightarrow r2$	// r1 r2	
mult	r1, r2	$\Rightarrow r3$	// r1 r2 r3	
loadI	x	$\Rightarrow r4$	// r1 r2 r3 r4	
sub	r4, r2	$\Rightarrow r5$	// r1 r3 r5	
loadI	z	$\Rightarrow r6$	// r1 r3 r5 r6	
mult	r5, r6	$\Rightarrow r7$	// r1 r3	r7
sub	r7, r3	$\Rightarrow r8$	// r1	r8
store	r8	$\Rightarrow r1$	//	

All registers are used
at this point

Note that this assumes that no extra register is needed for spilling

An Example

Bottom up (3 registers; need 2 for operands)

loadI	1028	$\Rightarrow r1$	// r1	
load	r1	$\Rightarrow r2$	// r1 r2	
mult	r1, r2	$\Rightarrow r3$	// r1 r2 r3	
loadI	x	$\Rightarrow r4$	// r1 r2 r3 r4	
sub	r4, r2	$\Rightarrow r5$	// r1 r3 r5	store r1
loadI	z	$\Rightarrow r6$	// r1 r3 r5 r6	
mult	r5, r6	$\Rightarrow r7$	// r1 r3	r7
sub	r7, r3	$\Rightarrow r8$	// r1	
store	r8	$\Rightarrow r1$	//	restore r1

Note that this assumes that no extra register is needed for spilling

An Example

Bottom up (3 registers; need 2 for operands)

loadI	1028	$\Rightarrow r1$	// r1	
load	r1	$\Rightarrow r2$	// r1 r2	
mult	r1, r2	$\Rightarrow r3$	// r1 r2 r3	
store	r1	$\Rightarrow 20$	// r2 r3	
loadI	x	$\Rightarrow r4$	// r2 r3 r4	
sub	r4, r2	$\Rightarrow r5$	// r3 r5	At most 3 values live at each point
loadI	z	$\Rightarrow r6$	// r3 r5 r6	
mult	r5, r6	$\Rightarrow r7$	// r3 r7	
sub	r7, r3	$\Rightarrow r8$	// r8	
load	20	$\Rightarrow r1$	// r1 r8	
store	r8	$\Rightarrow r1$	//	

The two short versions of r1 each overlap with fewer values, which simplifies the allocation problem. Such "spilling" will (eventually) create a code where the allocator can succeed.

Live Ranges in a single block

Your allocator is not bound by the names used in its input

- Every computed value is part of some live range
 - Even if it has no name in the source code (e.g., $2 * y$ in $x - 2 * y$)
- A live range usually has a single name, such as r_{17}
- A single name (SSA!) with multiple values can be renamed into distinct live ranges

Operation			Live Ranges	
loadI	@base	$\Rightarrow r_{arp}$	none	[1,11] 1
loadAI	$r_{arp}, @a$	$\Rightarrow r_a$	r_{arp}, r_a	[2,7] 2
loadI	2	$\Rightarrow r_2$	r_{arp}, r_a, r_2	[3,7] 3
loadAI	$r_{arp}, @b$	$\Rightarrow r_b$	r_{arp}, r_a, r_2	[4,8] 4
loadAI	$r_{arp}, @c$	$\Rightarrow r_c$	r_{arp}, r_a, r_b, r_2	[5,9] 5
loadAI	$r_{arp}, @d$	$\Rightarrow r_d$	$r_{arp}, r_a, r_c, r_b, r_2$	[6,10] 6
mult	r_a, r_2	$\Rightarrow r_a$	$r_{arp}, r_a, r_d, r_c, r_b, r_2$	[7,8] 7
mult	r_a, r_b	$\Rightarrow r_a$	$r_{arp}, r_a, r_d, r_c, r_b$	[8,9] 8
mult	r_a, r_c	$\Rightarrow r_a$	r_{arp}, r_a, r_d, r_c	[9,10] 9
mult	r_a, r_d	$\Rightarrow r_a$	r_{arp}, r_a, r_d	[10,11] 10
storeAI	r_a	$\Rightarrow r_{arp}, @w$	There are five distinct values, or live ranges, named r_a	

$$MEM(r1) \leftarrow z \cdot (x - y) - (1028 \cdot y)$$

Live Ranges

Your allocator is not bound by the names used in its input

- Every computed value is part of some live range
 - Even if it has no name in the source code (e.g., $2 * y$ in $x - 2 * y$)
- A live range usually has a single name, such as r_{17}
- A single name with multiple values can be renamed into distinct live ranges
- Renaming distinct live ranges with distinct names can simplify the implementation of the allocator
