# Superseding Traditional Indexes with Multicriteria Data Structures

GIORGIO VINCIGUERRA

PhD student in Computer Science giorgio.vinciguerra@phd.unipi.it

# Outline

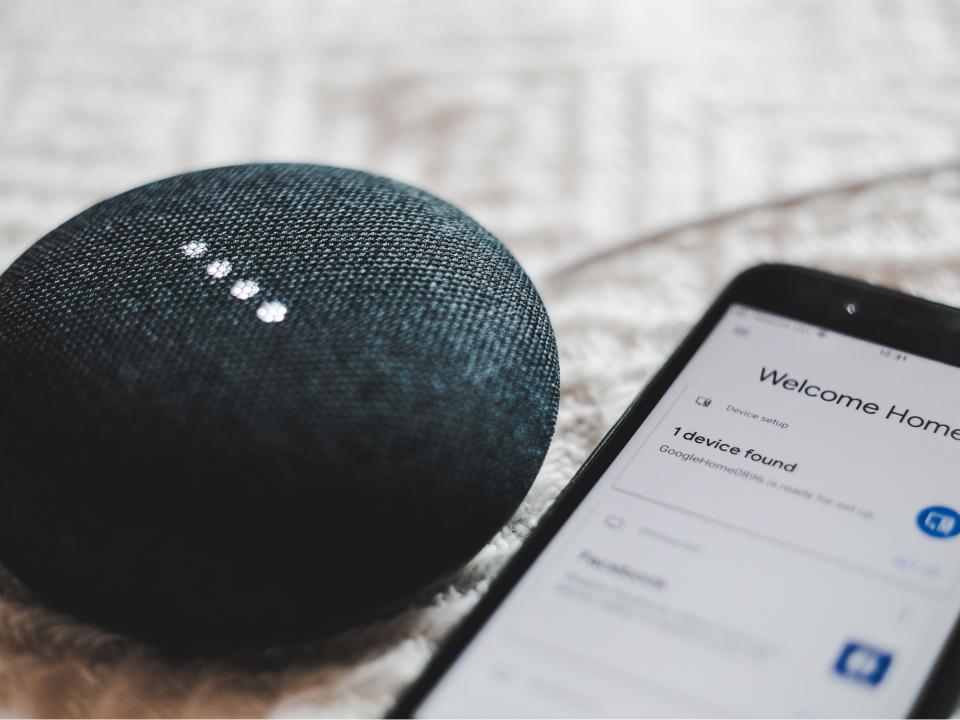

1. Multicriteria data structures

- 2. The dictionary problem
  - External memory model
  - Multiway trees
  - Novel approaches
  - Our results
- 3. Bonus slides

# Motivation

- 1. Algorithms and data structures often offer a collection of different trade-offs (e.g. time, space occupancy, energy consumption, ...)
- 2. Software engineers have to choose the one that best fits the needs of their application
- 3. These needs change with time, data, devices, and users

#### **Multicriteria Data Structures**

A *multicriteria data structure* selects the best data structure within some performance and computational constraints

**FAMILY** of data structures

**CONSTRAINTS** space, time, energy...

# The dictionary problem

We are given a set of "objects", and we are asked to store them succinctly and to support efficient retrieval

#### **B-trees are everywhere**

- 1. "B-trees have become, de facto, a standard for file organization" Comer. Ubiquitous B-tree. ACM Computing Surveys. '79
- 2. This is still true today

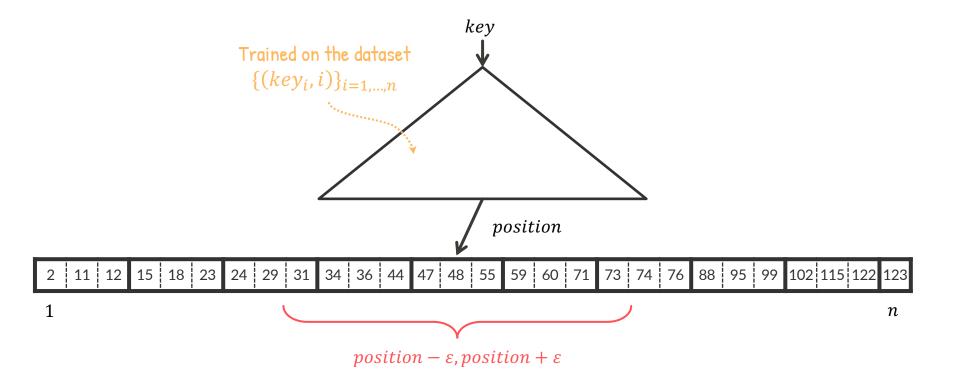

#### 

#### **B-trees are machine learning models**

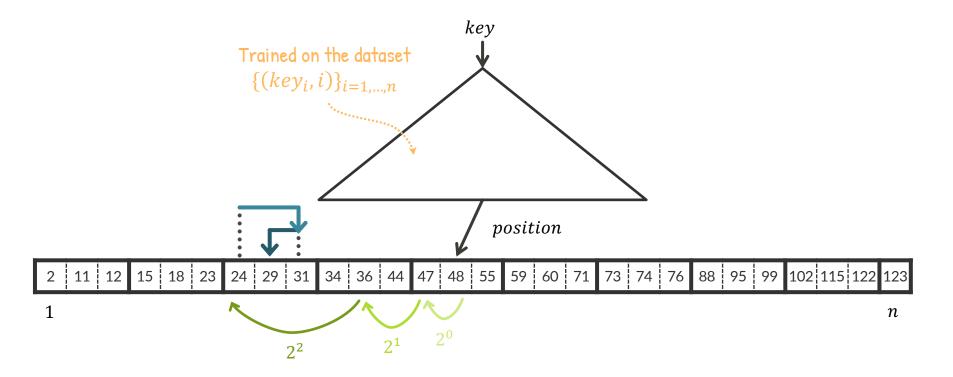

"All existing index structures can be replaced with other types of models, including deep-learning models, which we term learned indexes."

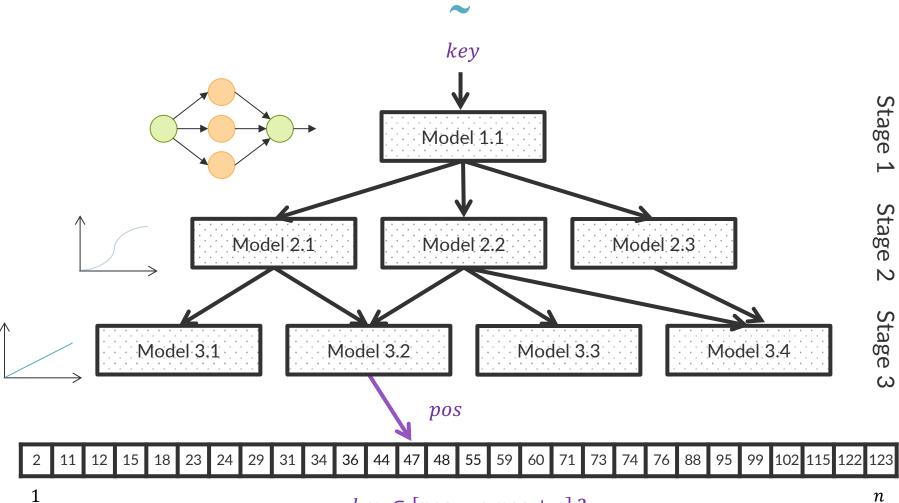

#### **B-trees are machine learning models**

"All existing index structures can be replaced with other types of models, including deep-learning models, which we term learned indexes."

#### The Recursive Model Index (RMI)

 $key \in [pos - \varepsilon, pos + \varepsilon]?$ 

# **Construction of RMI**

- 1. Train the root model on the dataset
- 2. Use it to distribute keys to the next stage
- 3. Repeat for each model in the next stage (on smaller datasets)

Stage 1 Stage 2

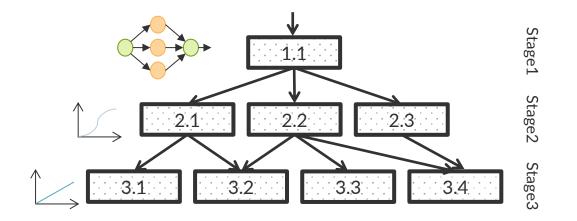

#### **Performance of RMI**

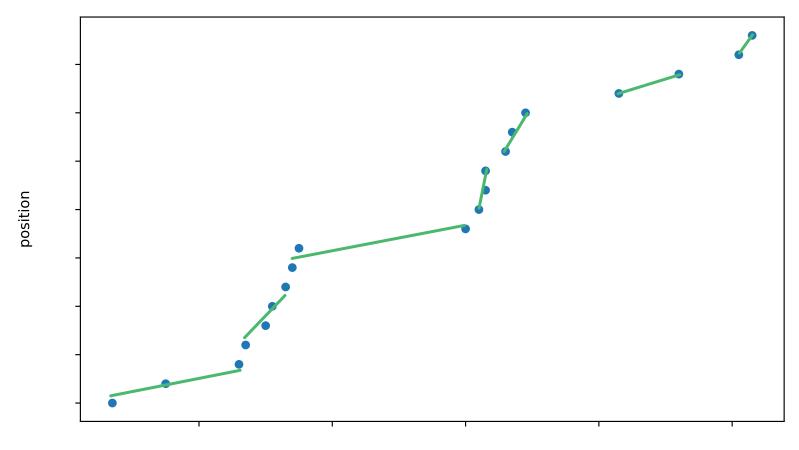

Figure 4: Learned Index vs B-Tree

# **Limitations of RMI**

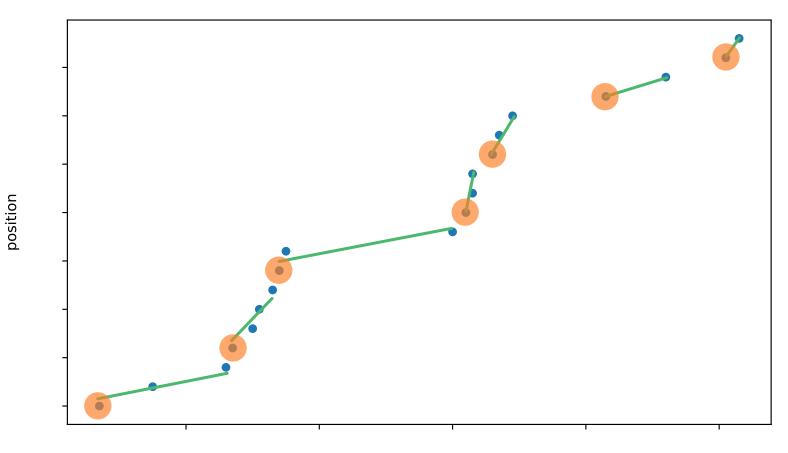

- 1. Fixed structure with many hyperparameters # stages, # models in each stage, kinds of regression models
- 2. No a priori error guarantees Difficult to predict latencies
- 3. Models are agnostic to the power of models below Can result in underused models (waste of space)

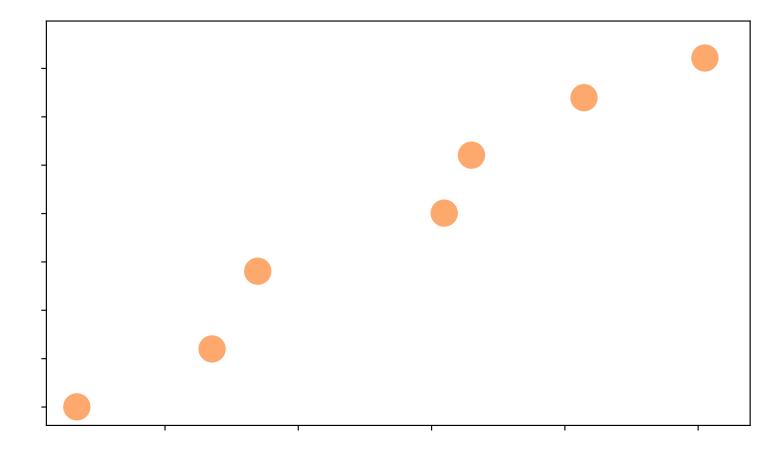

Compute the **optimal** piecewise linear approx with **guaranteed error**  $\varepsilon$  in O(n)

Save the *m* segments in a vector as triples  $s_i = (key, slope, intercept)$ 

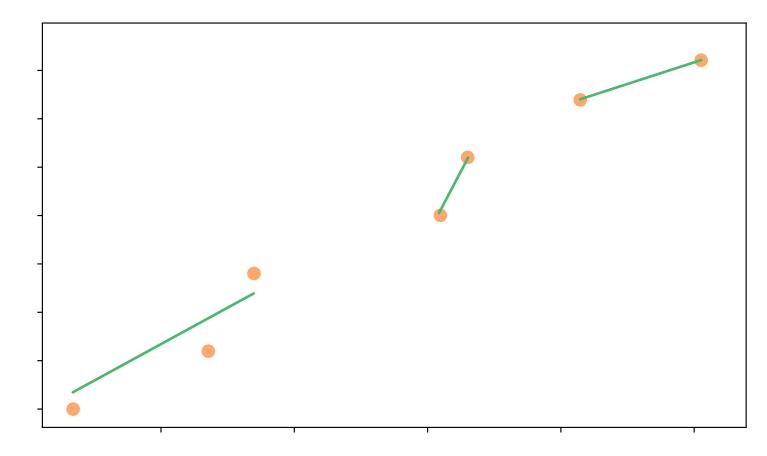

Drop all the points except  $s_i$ . key

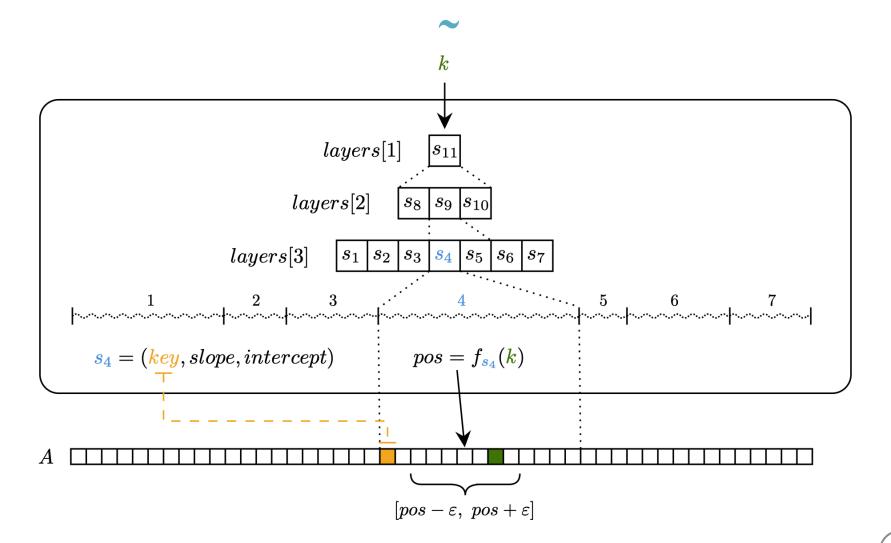

... and repeat!

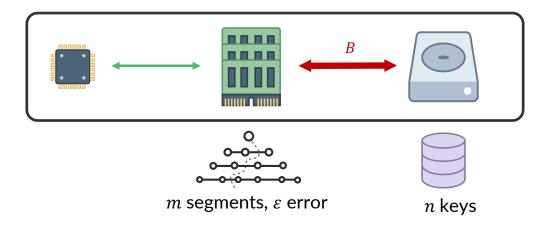

#### Memory layout of the PGM-index

### **PGM-index in practice**

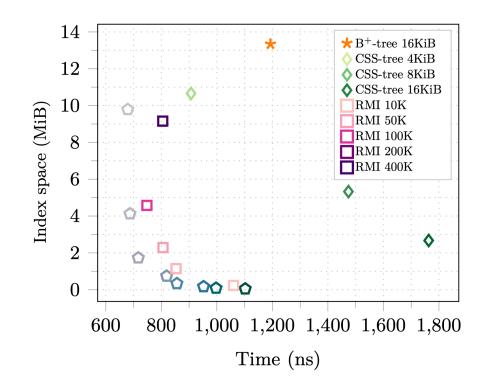

#### **Space-time performance**

## How to explore this space of trade-offs?

Given a space bound *S*, find efficiently the index that minimizes the query time within space *S* and vice versa

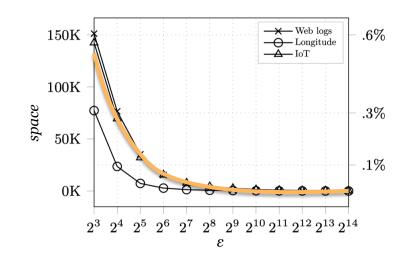

### **Back to Multicriteria Data Structures**

A multicriteria data structure is defined by a family of data structures and an optimisation algorithm that selects the best data structure in the family within some computational constraints

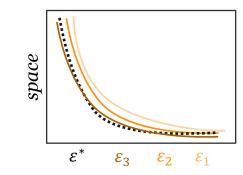

### **The Multicriteria PGM-index**

- 1. We designed a cost model for the space  $s(\varepsilon)$  and the time  $t(\varepsilon)$
- 2. ... but we don't have a closed formula for  $s(\varepsilon)$ , it depends on the input array
- 3. We fit  $s(\varepsilon)$  with a power law of the form  $a\varepsilon^{-b}$

### Under the hood

- 1. A sort of interpolation search over  $\varepsilon$  values
- 2. Each iteration improves the fitting of  $a\varepsilon^{-b}$  updating a, b
- 3. Bias the  $\varepsilon$ -iterate towards the midpoint of a bin. search
- In practice, given a space (time) bound, it finds the fastest (most compact) index for 715M keys in < 1 min</li>

#### **Future work**

- 1. Insertion and deletions
- 2. Non-linear models
- 3. Compression
