**AP-11:** *Java Generics*

# Outline

- Java generics
- Type bounds
- Generics and subtyping
- Covariance, contravariance in Java and other languages
- Subtyping and arrays in Java
- Wildcards
- Type erasure
- Limitations of generics

# Classification of Polymorphism

# Java Generics

## Explicit Parametric Polymorphism

- Classes, Interfaces, Methods can have type parameters
- The type parameters can be used arbitrarily in the definition
- They can be instantiated by providing arbitrary (reference) type arguments
- We discuss only a few issues about Java generics...

```
interface List<E> {  
    boolean add(E n);  
    E get(int index);  
}
```

```
List<Integer>  
List<Number>  
List<String>  
List<List<String>>  
...
```

Tutorials on Java generics:

<https://docs.oracle.com/javase/tutorial/java/generics/index.html>  
<http://thegreyblog.blogspot.it/2011/03/java-generics-tutorial-part-i-basics.html>

# Generic methods

- Methods can use the type parameters of the class where they are defined, if any
- They can also introduce their own type parameters

```
public static <T> T getFirst(List<T> list)
```

- Invocations of generic methods must instantiate all type parameters, either explicitly or implicitly
  - A form of **type inference**

# Bounded Type Parameters

```
class NumList<E extends Number> {  
    void m(E arg) {  
        arg.intValue(); // OK, Number and its  
                        // subtypes support intValue()  
    }  
}
```

- Only classes implementing **Number** can be used as type arguments
- Method defined in the bound (**Number**) can be invoked on objects of the type parameter

# Type Bounds

**<TypeVar extends SuperType>**

- *upper bound*; SuperType and any of its subtype are ok.

**<TypeVar extends ClassA & InterfaceB & InterfaceC & ...>**

- *Multiple* upper bounds

**<TypeVar super SubType>**

- *lower bound*; SubType and any of its supertype are ok

- Type bounds for methods guarantee that the type argument supports the operations used in the method body
- Unlike C++ where overloading is resolved and can fail after instantiating a template, in Java type checking ensures that overloading will succeed

# A generic algorithm with type bounds

```
public static <T> int countGreaterThan(T[] anArray, T elem) {  
    int count = 0;  
    for (T e : anArray)  
        if (e > elem) // compiler error  
            ++count;  
    return count;  
}
```

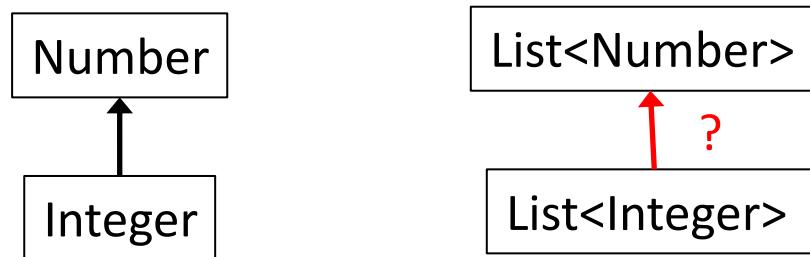

```
public interface Comparable<T> { // classes implementing  
    public int compareTo(T o); // Comparable provide a  
} // default way to compare their objects
```

```
public static <T extends Comparable<T>>  
    int countGreaterThan(T[] anArray, T elem) {  
        int count = 0;  
        for (T e : anArray)  
            if (e.compareTo(elem) > 0) // ok, it compiles  
                ++count;  
        return count;  
    }
```

# Generics and other language features

- Introduction of generics in Java 5 has been pervasive
  - All the API were “generified”
  - Backward compatibility thanks to “type erasure”
- Generics are compatible with most language features, but not all.
- We discuss the problems caused by the introduction of generics with respect two important aspects of Java (and other languages):
  - Inheritance (subtyping)
  - Arrays

# Generics and subtyping

- **Integer** is subtype of **Number**
- Is **List<Integer>** subtype of **List<Number>?**
- NO!

# What are Java rules?

- Given two concrete types **A** and **B**, **MyClass<A>** has **no relationship** to **MyClass<B>**, regardless of whether or not **A** and **B** are related.
- Formally: subtyping in Java is **invariant** for generic classes.
- Note: The common parent of **MyClass<A>** and **MyClass<B>** is **MyClass<?>**: the “wildcard” **?** Will be discussed later.
- On the other hand, as expected, if **A** extends **B** and they are generic classes, for each type **C** we have that **A<C>** extends **B<C>**.
- Thus, for example, **ArrayList<Integer>** is subtype of **List<Integer>**

```
void sort(List<Number> l){  
    // efficient sorting for numbers  
}  
...  
List<Integer> lisInt = new ArrayList<Integer>();  
// initialize the list of integers  
sort(lisInt);    // does not compile
```

# List<Number> e List<Integer>

```
interface List<T> {  
    boolean add(T elt);  
    T get(int index);  
}
```

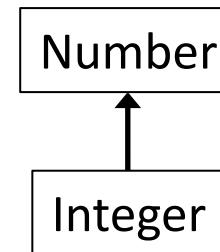

type List<Number> has:

```
boolean add(Number elt);  
Number get(int index);
```

type List<Integer> has:

```
boolean add(Integer elt);  
Integer get(int index);
```

```
List<Integer> lisInt = new ...;  
List<Number> lisNum = new ...;  
lisNum = lisInt; // ???  
lisNum.add(new Number(...)); //no  
listInt = lisNum; // ???  
Integer n = lisInt.get(0); //no
```

Is the **Substitution Principle** satisfied in either direction?

Thus List<Number> is neither a supertype nor a subtype of List<Integer>. Java rules are adequate here

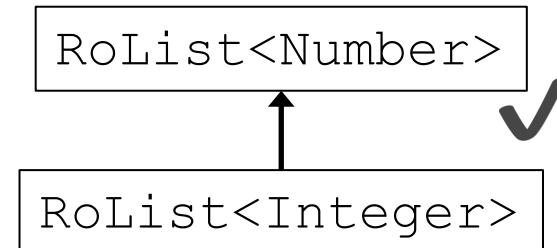

# But in more specific situations...

```
interface RoList<T> {  
    T get(int index);  
}
```

```
type RoList<Number>;  
    Number get(int index);
```

```
type RoList<Integer>;  
    Integer get(int index);
```

```
RoList<Integer> lisInt = new ...;  
RoList<Number> lisNum = new ...;  
lisNum = lisInt;      // ???  
Number n = lisNum.get(0); //ok
```

A **covariant** notion of subtyping would be safe:

- **RoList<Integer>** can be subtype of **RoList<Number>**
- Not in Java
- In general: **covariance** is safe if the type is **read-only**

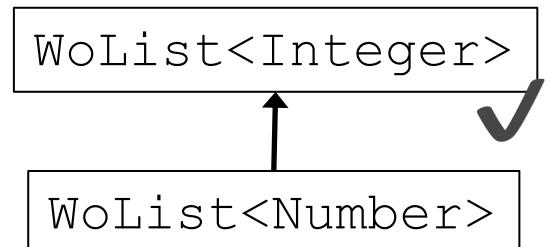

# Viceversa... contravariance!

```
interface WoList<T> {  
    boolean add(T elt);  
}
```

```
type WoList<Number>:  
    boolean add(Number elt);
```

```
type WoList<Integer>:  
    boolean add(Integer elt);
```

```
WoList<Integer> lisInt = new ...;  
WoList<Number> lisNum = new ...;  
lisInt = lisNum;      // ???  
lisInt.add(new Integer(...)); //ok
```

A **contravariant** notion of subtyping would be safe:

- **WoList<Number>** can be a subtype of **WoList<Integer>**
- But Java .....

In general: **contravariance** is safe if the type is **write-only**

# Generics and subtypes in C#

- In C#, the type parameter of a generic class can be annotated **out** (covariant) or **in** (contravariant), otherwise it is invariant.  
Examples:
- **IEnumerable** is covariant, because the only method returns an enumerator, which accesses the collection in read-only

```
public interface IEnumerable<out T> : [...] {  
    public [...] IEnumerator<out T> GetEnumerator();  
}
```

- **IComparable** is contravariant, because the only method has an argument of type **T**

```
public interface IComparable<in T> {  
    public int CompareTo (T other);  
}
```

# Co- and Contra-variance in Scala

- Also Scala supports co/contra-variance annotations (- and +) for type parameters:

```
class VendingMachine[+A] {...}
```

```
class GarbageCan[-A] {...}
```

```
trait Function1[-T, +R] extends AnyRef
{ def apply(v1: T): R }
```

<http://blog.kamkor.me/Covariance-And-Contravariance-In-Scala/>

# Arrays and generics

- Arrays are like built-in containers
  - Let **Type1** be a subtype of **Type2**.
  - How are **Type1 []** e **Type2 []** related?
- Consider the following generic class, mimicking arrays:

```
class Array<T> {  
    public T get(int i) { ... }  
    public T set(T newVal, int i) { ... }  
}
```

According with Java rules, **Array<Type1>** and **Array<Type2>** are not related by subtyping

# But instead...

- In Java, if **Type1** is a subtype of **Type2**, then **Type1 []** is a subtype of **Type2 []**. Thus Java arrays are **covariant**.
- Java (and also C#, .NET) fixed this rule before the introduction of generics.
- Why? Think to 

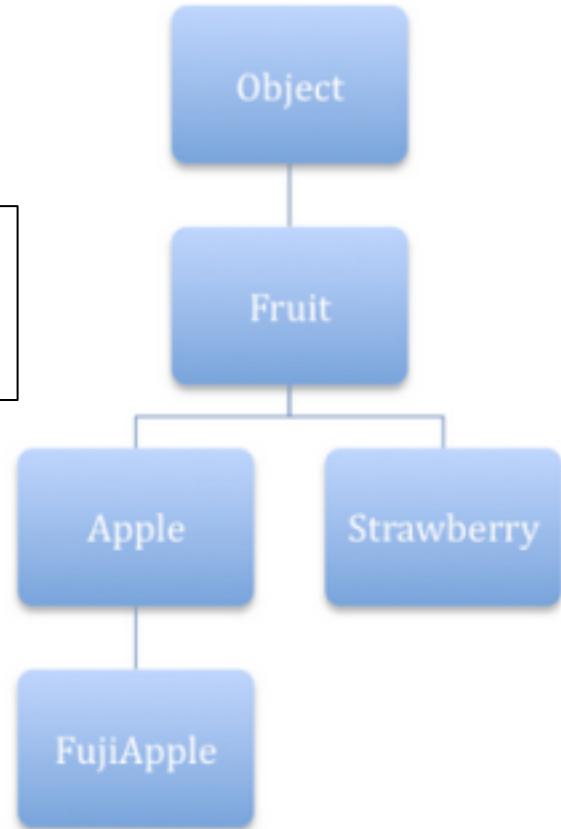

void sort(Object[] o);
- Without **covariance**, a new sort method is needed for each reference type different from Object!
- But sorting does not insert new objects in the array, thus it cannot cause type errors if used covariantly

# Problems with array covariance

Even if it works for `sort`, covariance may cause type errors in general

```
Apple[] apples = new Apple[1];
Fruit[] fruits = apples; //ok, covariance
fruits[0] = new Strawberry(); // compiles!
```

This breaks the general Java rule: For each reference variable, the **dynamic type** (type of the object referred by it) must be a **subtype** of the **static one** (type of declaration).

# Java's design choices

```
(1) Apple[] apples = new Apple[1];  
(2) Fruit[] fruits = apples; //ok, covariance  
(3) fruits[0] = new Strawberry(); // compiles!
```

- The dynamic type of an array is known at runtime
  - During execution the JVM knows that the array bound to `fruits` is of type `Apple []` (or better `[LApple;` in JVM type syntax)
- Every array update includes a **run-time check**
- Assigning to an array element an object of a non-compatible type throws an **ArrayStoreException**
  - Line (3) above throws an exception

# Recalling "Type erasure"

All type parameters of generic types are transformed to **Object** or **to their first bound** after compilation

- Main Reason: backward compatibility with legacy code
- Thus at run-time, all the instances of the same generic type have the same type

```
List<String> lst1 = new ArrayList<String>();  
List<Integer> lst2 = new ArrayList<Integer>();  
lst1.getClass() == lst2.getClass() // true
```

# Array covariance and generics

- Every Java array-update includes run-time check, but
- Generic types are not present at runtime due to **type erasure**, thus
- **Arrays of generics are not supported in Java**
- In fact they would cause type errors not detectable at runtime, **breaking Java strong type safety**

```
List<String>[ ] lsa = new List<String>[10]; // illegal  
Object[ ] oa = lsa; // OK by covariance of arrays  
  
List<Integer> li = new ArrayList<Integer>();  
li.add(new Integer(3));  
  
oa[0] = li; // should throw ArrayStoreException,  
// but JVM only sees "oa[0]:List = li:ArrayList"  
  
String s = lsa[0].get(0); // type error !!
```

# Wildcards for covariance

- Invariance of generic classes is restrictive
- Wildcards can alleviate the problem
- What is a “general enough” type for **addAll**?

```
interface Set<E> {  
    // Adds to this all elements of c  
    // (not already in this)  
    void addAll(??? c);  
}
```

- `void addAll(Set<E> c) // and List<E>?`
- `void addAll(Collection<E> c)`  
`// and collections of T <: E?`
- `void addAll(Collection<? extends E> c); // ok`

# Wildcards, for both co- and contra-variance

- wildcard = anonymous variable
  - `? Unknown type`
  - Wildcard are used when a type is used exactly once, and the name is unknown
  - They are used for **use-site variance** (not **declaration-site variance**)
- Syntax of wildcards:
  - `? extends Type`, denotes an unknown subtype of **Type**
  - `? ,` shorthand for `? extends Object`
  - `? super Type`, denotes an unknown supertype of **Type**

# The “PECS principle”: Producer Extends, Consumer Super

When should wildcards be used?

- Use `? extends T` when you want to get values (from a producer): supports **covariance**
- Use `? super T` when you want to insert values (in a consumer): supports **contravariance**
- Do not use `? (T is enough)` when you both obtain and produce values.

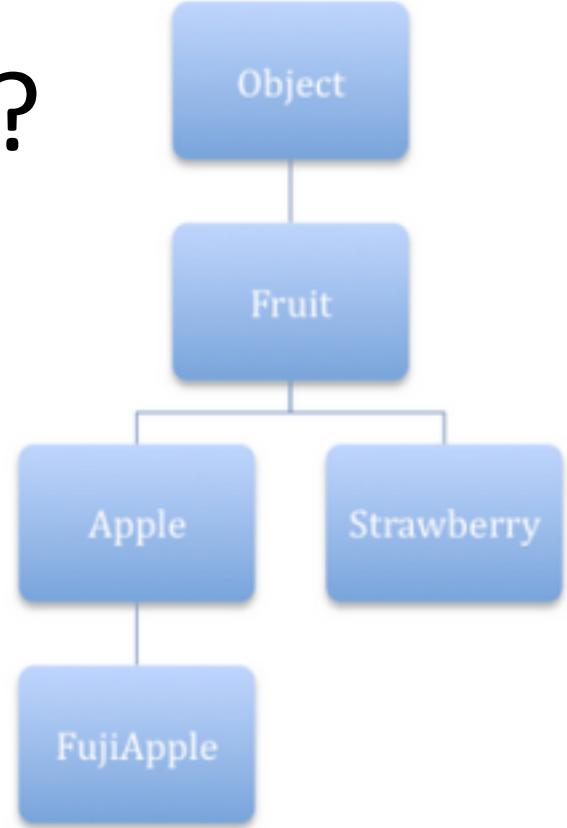

Example:

```
<T> void copy(List<? super T> dst,  
              List<? extends T> src);
```

# What about type safety?

- Arrays covariance:

```
Apple[] apples = new Apple[1];
Fruit[] fruits = apples;
fruits[0] = new Strawberry();
// JVM throws ArrayStoreException
```

- Covariance with wildcards:

```
List<Apple> apples = new ArrayList<Apple>();
List<? extends Fruit> fruits = apples;
fruits.add(new Strawberry());
// compile-time error!!!
```

# The price to pay with wildcards

- A wildcard type is anonymous/unknown, and almost nothing can be done:

```
List<Apple> apples = new ArrayList<Apple>();
List<? extends Fruit> fruits = apples; // covariance
fruits.add(new Strawberry()); // compile-time error! OK
Fruits f = fruits.get(0); // OK
fruits.add(new Apple()); // compile-time error???
fruits.add(null); // ok, the only thing you can add ☺
```

```
List<Fruit> fruits = new ArrayList<Fruits>();
List<? super Apples> apples = fruits; // contravariance
apples.add(new Apple()); // OK
apples.add(new FujiApple()); // OK
apples.add(new Fruit()); // compile-time error, OK
Fruits f = apples.get(0); // compile-time error???
Object o = apples.get(0); // ok, the only way to get
```

# Limitations of Java Generics

Mostly due to "Type Erasure":

- Cannot Instantiate Generic Types with Primitive Types

```
ArrayList<int> a = ... //does not compile
```

- Cannot Create Instances of Type Parameters
- Cannot Declare Static Fields Whose Types are Type Parameters

```
public class C<T>{ public static T local; ...}
```

- Cannot Use **casts** or **instanceof** With Parameterized Types

```
(list instanceof ArrayList<Integer>) // does not compile
```

```
(list instanceof ArrayList<?>) // ok
```

- Cannot Create Arrays of Parameterized Types
- Cannot Create, Catch, or Throw Objects of Parameterized Types
- Cannot Overload a Method Where the Formal Parameter Types of Each Overload Erase to the Same Raw Type

```
public class Example { // does not compile
public void print(Set<String> strSet) { }
public void print(Set<Integer> intSet) { } }
```
